1. Introduction

Laser Induced Breakdown Spectroscopy (LIBS) has been developed for the effective and efficient safeguards of pyroprocessing at Korea Atomic Energy Research Institute (KAERI) [1]. LIBS is based on the optical analysis of the plasma generated by concentrating a strong laser beam on the surface of the sample. LIBS has characteristic such as real-time analysis, no sample preparation before the analysis, and possibility of situ implementation.[2-5] In this study, U and lanthanide element in LiCl - KCl salt are measured as electrorefining process material of pyroprocessing via LIBS. In this study, LiCl - KCl based salts LaCl₃, CeCl₃, BaCl₂, PrCl₃, NdCl₃, YCl₃, SmCl₃ and UCl₃ were added and melted and then sampled the salt in the solid state was measured in order to reduce the measurement error. The purpose of the present study is to explore the applicability of LIBS to quantitatively measure the uranium in the electrorefining salt.

2. Methods and Results

At first, five LiCl-KCl samples containing UCl₃ were fabricated to obtain the preliminary calibration curve. Sample contained from 1.5wt% to 6.8wt% UCl₃. Composition materials of the samples were placed in the glassy carbon crucible, and they were heated up to 650 °C to melt. The molten salt samples were slowly cooled to solid form in the furnace.

Experiments were conducted in a glove box with an atmosphere of Ar gas with moisture and oxygen content of 100 ppm or less for samples with high deliquescence. The LIBS measurement setup is shown in Figure 1. A laser beam was injected through the port of the glove box and the optical fiber cable was inserted I received it. The sample surface was somewhat irregular and the distance between the sample and the focusing lens was corrected each time the sample surface was changed by interlocking the XYZ moving sample table with a high precision distance meter to match the same focal length.

A beam of Q-switched Nd: YAG pulse laser (Brilliant B, Quantel) with a wavelength of 532 nm is focused on the sample surface to generate plasma and Echelle spectroscopy with 20,000($\lambda/\Delta\lambda$) resolution to detect plasma emission line and ICCD camera was used. The emission lines of U and other emission line were

selected in the wavelength region of 200 to 400 nm where spectroscopy is permitted. The number of laser pulses in the measurement was 100. After collecting of LIBS spectrum at a position, the sample was moved horizontally to obtain the scan data of the sample surface. The measured U spectrum in the wavelength 357.005nm, 294.189nm, 297.101nm, 304.403nm and 385.952nm were analyzed. The U peak intensity is normalized with peak intensity of the K 399.180 nm line. Figure 2 is the LIBS spectrum of 356.5 nm to 357.5 nm range, clearly shows the 356.654 nm peak and 357.005 nm peak are from U. Figure 2 shows a spectrum of the Comparison of U with varying concentration sample and the sample without U.

Fig. 1. LIBS system used in the present work

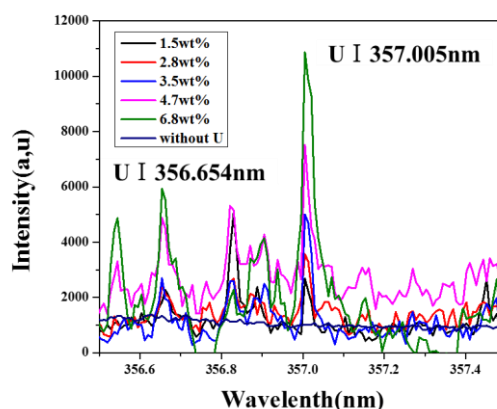

Fig. 2. U spectrum in a sample containing from 1.5 wt% to 6.8 wt% UCl₃ in LiCl-KCl.

The U 385.952 nm line had the smallest Limits of detection (LOD,) 0.0576wt%, and the 304.413nm line had the highest LOD, 0.1820wt%. For better analysis of

74 the performances, Partial least-squares (PLS) regression
75 modeling was also conducted to obtain a multivariate
76 calibration curve. The root mean squares error of
77 calibration (RMSEC) for the U model as a function of
78 the latent variables used are shown in Figure 3a. In this
79 case seven latent variables were used to best capture the
80 behavior of the spectral data. The PLS calibration curve
81 for U is shown in Figure 3b. The RMSEC is 0.4152wt%,
82 which is smaller than the univariate case.

89 3. Summary

90
91 LIBS is a promising technology as the process
92 monitoring technology applicable to the pyroprocessing
93 safeguards. The uranium concentration in LiCl-KCl salt
94 were measured using LIBS system, and the quantitative
95 analysis performance of LIBS. U concentrations in the
96 samples ranged from 1.5 wt% to 6.8 wt%, and the
97 achieved values of accuracy and LOD are 2 ~ 8 % and
98 0.0576wt% respectively. Our result is promising for
99 application of the LIBS to the safeguards. Between the
100 univariate and the PLS analysis, the univariate approach
101 showed better results. The benefit of the PLS grows as
102 the spectrum get complex, and PLS analysis will play
103 important role in the salt analysis of the spent fuel
104 processed salt.
